Abstract

Preliminary clinical evidence suggests that metformin has TSH lowering effects in patients with T2DM and hypothyroidism or in those with TSH serum levels in the upper normal value. Also, metformin may exert a protective role against thyroid nodules growth in patients without insulin-resistance. The cross-talk between tyrosine kinase receptors and the G protein-coupled receptors (which the TSHR belongs to) has been already shown and IRS1 may represent the hub link between TSHR and IR pathways. By influencing IRS1 phosphorylation pattern, metformin may sensitize TSHR to TSH, thus explaining the findings of clinical studies. However, the existence of this molecular pathway must be confirmed through proper studies and further prospective randomized placebo-controlled studies are needed to confirm this hypothesis.

37 Thyroid disease, obesity and type II diabetes mellitus (T2DM) represent the more common endocrine
1 disorders. They are often concomitantly present in the same patient. Particularly, the prevalence of
238 3 hypothyroidism in patients with T2DM is about 10-15% [1,2]. Thus, the prescription of insulin-sensitizing
439 5 drugs and, first of all, of metformin, is not infrequent among patients with hypothyroidism, goiter and thyroid
640 7 nodules. This has led to consider the effects of metformin on thyroid disorders, including serum thyroid
841 stimulating hormone (TSH) and free thyroxine (FT4) levels and thyroid nodules, resulting in the publication
10 of a relevant number of studies in the last two decades. We used the key-words “metformin” and “TSH
142 12 lowering effects”, to retrieve articles providing us with data useful to clarify the relationship between
1343 14 metformin and thyroid function.
1544 16
1745 18
19
20

2146 In a prospective study-design, 101 patients with T2DM were treated with metformin. Among these,
22 2347 24 29 hypothyroid patients were treated with levo-thyroxine (LT4), 18 hypothyroid patients did not receive LT4
2548 26 and 54 were euthyroid patients. After 1 year of metformin administration, a significant decrease in TSH serum
2749 28 levels was reported in patients with T2DM and hypothyroidism (n=47). No change was found in euthyroid
29 patients. Furthermore, serum FT4 levels were not affected. Interestingly, the body mass index (BMI) did not
3050 differ following metformin administration, thus excluding a role for body weight decrease in the TSH lowering
31 effect of metformin, especially in LT4 treated patients [3]. In the same study, a short-term administration of
3251 33 metformin (up to 24 weeks) did not affect TSH serum levels in 11 patients with T2DM and hypothyroidism
3452 35 receiving LT4 [3]. The TSH lowering effects of metformin were confirmed also elsewhere, although in a
3653 37 limited number of patients [4].
38
3954 40
4155 42
43

4456 In euthyroid patients with T2DM, metformin seems to lower serum TSH levels in those with values in
45 the upper quartile. Accordingly, a retrospective study on 250 euthyroid patients with T2DM failed to confirm
4657 47 the TSH lowering effect of metformin. However, TSH values were not analyzed according to baseline quartile
4858 49 [5]. By contrast, a retrospective study on 393 euthyroid patients with T2DM divided the patients in three
50 groups: the first did not receive neither metformin nor LT4 (n=119); the second group received only metformin
5159 52 (n=203); the third group received both metformin and LT4 (n=71). Treatment was prescribed for at least 1
5360 54 year. The results showed a significant decrease of serum TSH levels, independently of pre-treatment values,
5561 56 in the third group, which received LT4 at replacement doses. A significant reduction of serum TSH levels was
5762 58
5963 60
61
62
63
64
65

64 observed also in euthyroid patients with high-normal pre-treatment TSH values (from 3.24 ± 0.51 to 2.27 ± 1.28
1 mU/l) belonging to the second group, which did not take LT4 [6]. At the multivariate regression analysis, these
265 findings were independent from the BMI and from the presence of thyroid peroxidase antibodies. Furthermore,
3
466 no change of TSH levels were observed in patients of the first group, which did not receive neither metformin
5
67 or LT4 [6]. Finally, a recent meta-analysis of six randomized controlled clinical trials including 494 euthyroid
8
98 patients confirmed the TSH lowering effect of metformin after one year of treatment but not after 3 and 6
10
169 months [7]. Only one clinical study suggested a protective role of metformin on thyroid nodules growth in
12
1370 patients without insulin-resistance [8].
14
1571

16
17
1872 Taken together, these findings suggest that the long-term administration of metformin is able to lower serum
19
20
2173 TSH levels, selectively in patients with T2DM and hypothyroidism and in those with euthyroidism and TSH
22
2374 in the upper-normal quartile. Accordingly, these effects have not been observed in another clinical model:
24
2575 patients with polycystic ovarian syndrome (PCOS) [9,10].
26

27
2876 Several molecular mechanisms have been called into play to explain the TSH lowering effects of
29
30
3177 metformin. Some authors have suggested the increase of the central dopaminergic tone, the change of the
32
3378 affinity or the expression of thyroid hormone receptor or an effect on TSH regulation as possible explanatory
34
3579 mechanisms [11,12].
36

37
3880 TSH receptor (TSHR) is a protein made of two subunits, the α and the β , whose activation leads to the
39
4081 increase of intracellular adenylate cyclase levels. Follicle-stimulating hormone receptor (FSHR) and
41
42
4382 luteinizing-hormone receptor (LHR) share the same α subunit, and differ for the β subunit, which is receptor-
44
4583 specific. Molecular signaling of these three receptors is similar, since they belong to the G protein-coupled
46
4784 receptor family [13]. Interestingly, the existence of a cross-talk between the tyrosine kinase receptors [e.g.
48
4985 insulin receptor (IR), insulin-like growth one receptor (IGF1R)] and the G protein-coupled receptors has been
50
5186 demonstrated [14]. Specifically, an *in-vitro* study on mice granulosa cells showed that insulin receptor
52
53
5487 substrate 1 (IRS1) as the hub linking between the FSHR and the IGF1R-mediated activation of
55
5688 phosphatidylinositol 3-kinase (PI-3K) [15]. More in detail, the incubation with FSH and the consequent FSHR-
57
5889 dependent increase of protein kinase A (PKA) activates the protein phosphatase 1β (PP1 β), a ubiquitous
59
6090 eukaryotic Ser/Thr phosphatase, and the change in phosphorylation of specific domains of IRS1, thus leading
61

91 to the IGF1R auto-phosphorylation [16] (**Figure 1, panel A**). This pathway has also been confirmed in an
1 experimental model of prepubertal porcine Sertoli cells [17]. Fascinatingly, patients with insulin-resistance
292 show abnormally phosphorylated IRS1, which hinders the IR-dependent signaling cascade. The abnormal
3 show abnormally phosphorylated IRS1, which hinders the IR-dependent signaling cascade. The abnormal
493 IRS1 phosphorylation may hypothetically interfere also with the signaling pathway of the G protein-coupled
5 IRS1 phosphorylation may hypothetically interfere also with the signaling pathway of the G protein-coupled
694 receptors, namely FSHR, LHR and TSHR. Accordingly, patients with insulin-resistance show a poorer
7 response to FSH administration compared to patients with insulin-resistance but concomitantly treated with
8 response to FSH administration compared to patients with insulin-resistance but concomitantly treated with
95 metformin [18]. We hypothesize that the abnormal phosphorylation of IRS1 occurring in patients with T2DM
